Package: semTests (via r-universe)

September 18, 2024

Type Package

Title Goodness-of-Fit Testing for Structural Equation Models

Description Supports eigenvalue block-averaging p-values (Foldnes, Grønneberg, 2018) <doi:10.1080/10705511.2017.1373021>, penalized eigenvalue block-averaging p-values (Foldnes, Moss, Grønneberg, WIP), penalized regression p-values (Foldnes, Moss, Grønneberg, WIP), as well as traditional p-values such as Satorra-Bentler. All p-values can be calculated using unbiased or biased gamma estimates (Du, Bentler, 2022) <doi:10.1080/10705511.2022.2063870> and two choices of chi square statistics.

`pvalues` *Calculate p-values for one or two lavaan objects.*

Description

Calculate p-values for a `lavaan` object using several methods, including penalized eigenvalue block-averaging and penalized regression estimators. The choice `peba=4` together with `chisq = "rls"` and `ub` is recommended. Multiple p-values can be returned simultaneously.

Usage

```
pvalues(
  object,
  trad = NULL,
  eba = NULL,
  peba = c(2, 4),
  pols = 2,
  unbiased = 1,
  chisq = c("rls", "trad"),
  extras = FALSE
)
```

Arguments

`object`	A `lavaan` object.
`trad`	List of traditional p-values to calculate. Not calculated if `NULL`.
`eba`	List of which `eba` p-values to calculate. Not calculated if `NULL`.
`peba`	List of which `peba` p-values to calculate. Not calculated if `NULL`.
`pols`	List of penalization parameters to use in the penalized OLS p-value. Not calculated if `NULL`.
`unbiased`	A number between 1 and 3. 1: Calculate using the biased gamma matrix (default). 2: Calculate using the unbiased gamma matrix. 3: Calculate using both gammas.
`chisq`	Which chi-square statistic to base the calculations on.
`extras`	Returns the estimated eigenvalues and basic test statistics if checked.

Details

The traditional methods include:

- `pstd` the standard *p*-value where the choice of `chisq` is approximated by a chi square distribution.
- `psb` Satorra-Bentler *p*-value. The *p*-value proposed by Satorra and Bentler (1994).
- `pss` The scaled and shifted *p*-value proposed by Asparouhov & Muthén (2010).
- `pcf` The Scaled F *p*-value proposed by Wu and Lin (2016).
- `pfull` *p*-value based on all eigenvalues of the asymptotic covariance matrix matrix.

The `eba` method partitions the eigenvalues into `j` equally sized sets (if not possible, the smallest set is incomplete), and takes the mean eigenvalue of these sets. Provide a list of integers `j` to partition with respect to. The method was proposed by Foldnes & Grønneberg (2018). `eba` with `j=2` or `j=4` appear to work best.

The `peba` method is a penalized variant of `eba`, described in (Foldnes, Moss, Grønneberg, WIP). It typically outperforms `eba`, and the best choice of `j` is typically `6`.

`pols` is a penalized regression method with a penalization term from ranging from 0 to infitity. Foldnes, Moss, Grønneberg (WIP) studied `pols=2`, which has good performance in a variety of contexts.

The `unbiased` argument is `TRUE` if the the unbiased estimator of the fourth order moment matrix (Du, Bentler, 2022) is used. If `FALSE`, the standard biased matrix is used. There is no simple relationship between p-value performance and the choice of `unbiased`.

The `chisq` argument controls which basic test statistic is used. The `trad` choice uses the chi square based on the normal discrepancy function (Bollen, 2014). The `rls` choice uses the reweighted least squares statistic of Browne (1974).

Value

A named vector of p-values.
